

The iGeo script creates [20] particles that randomly flow in parallel through digital space. Each particle trails [500] line segments behind it. The outer line segments randomly shoot out additional line segments that connect them with the inner line segments. The iGeo script can be altered to change the number of particles, their directionality, and the duration of their travels / number of line segments that they trail. The formal outcomes of these shifts vary infinitely - the ultimate objective being control over / intention for that variety.

## Particle Pachanga
